

# Seasonal to Decadal Predictions

Gabriel Vecchi – NOAA/GFDL

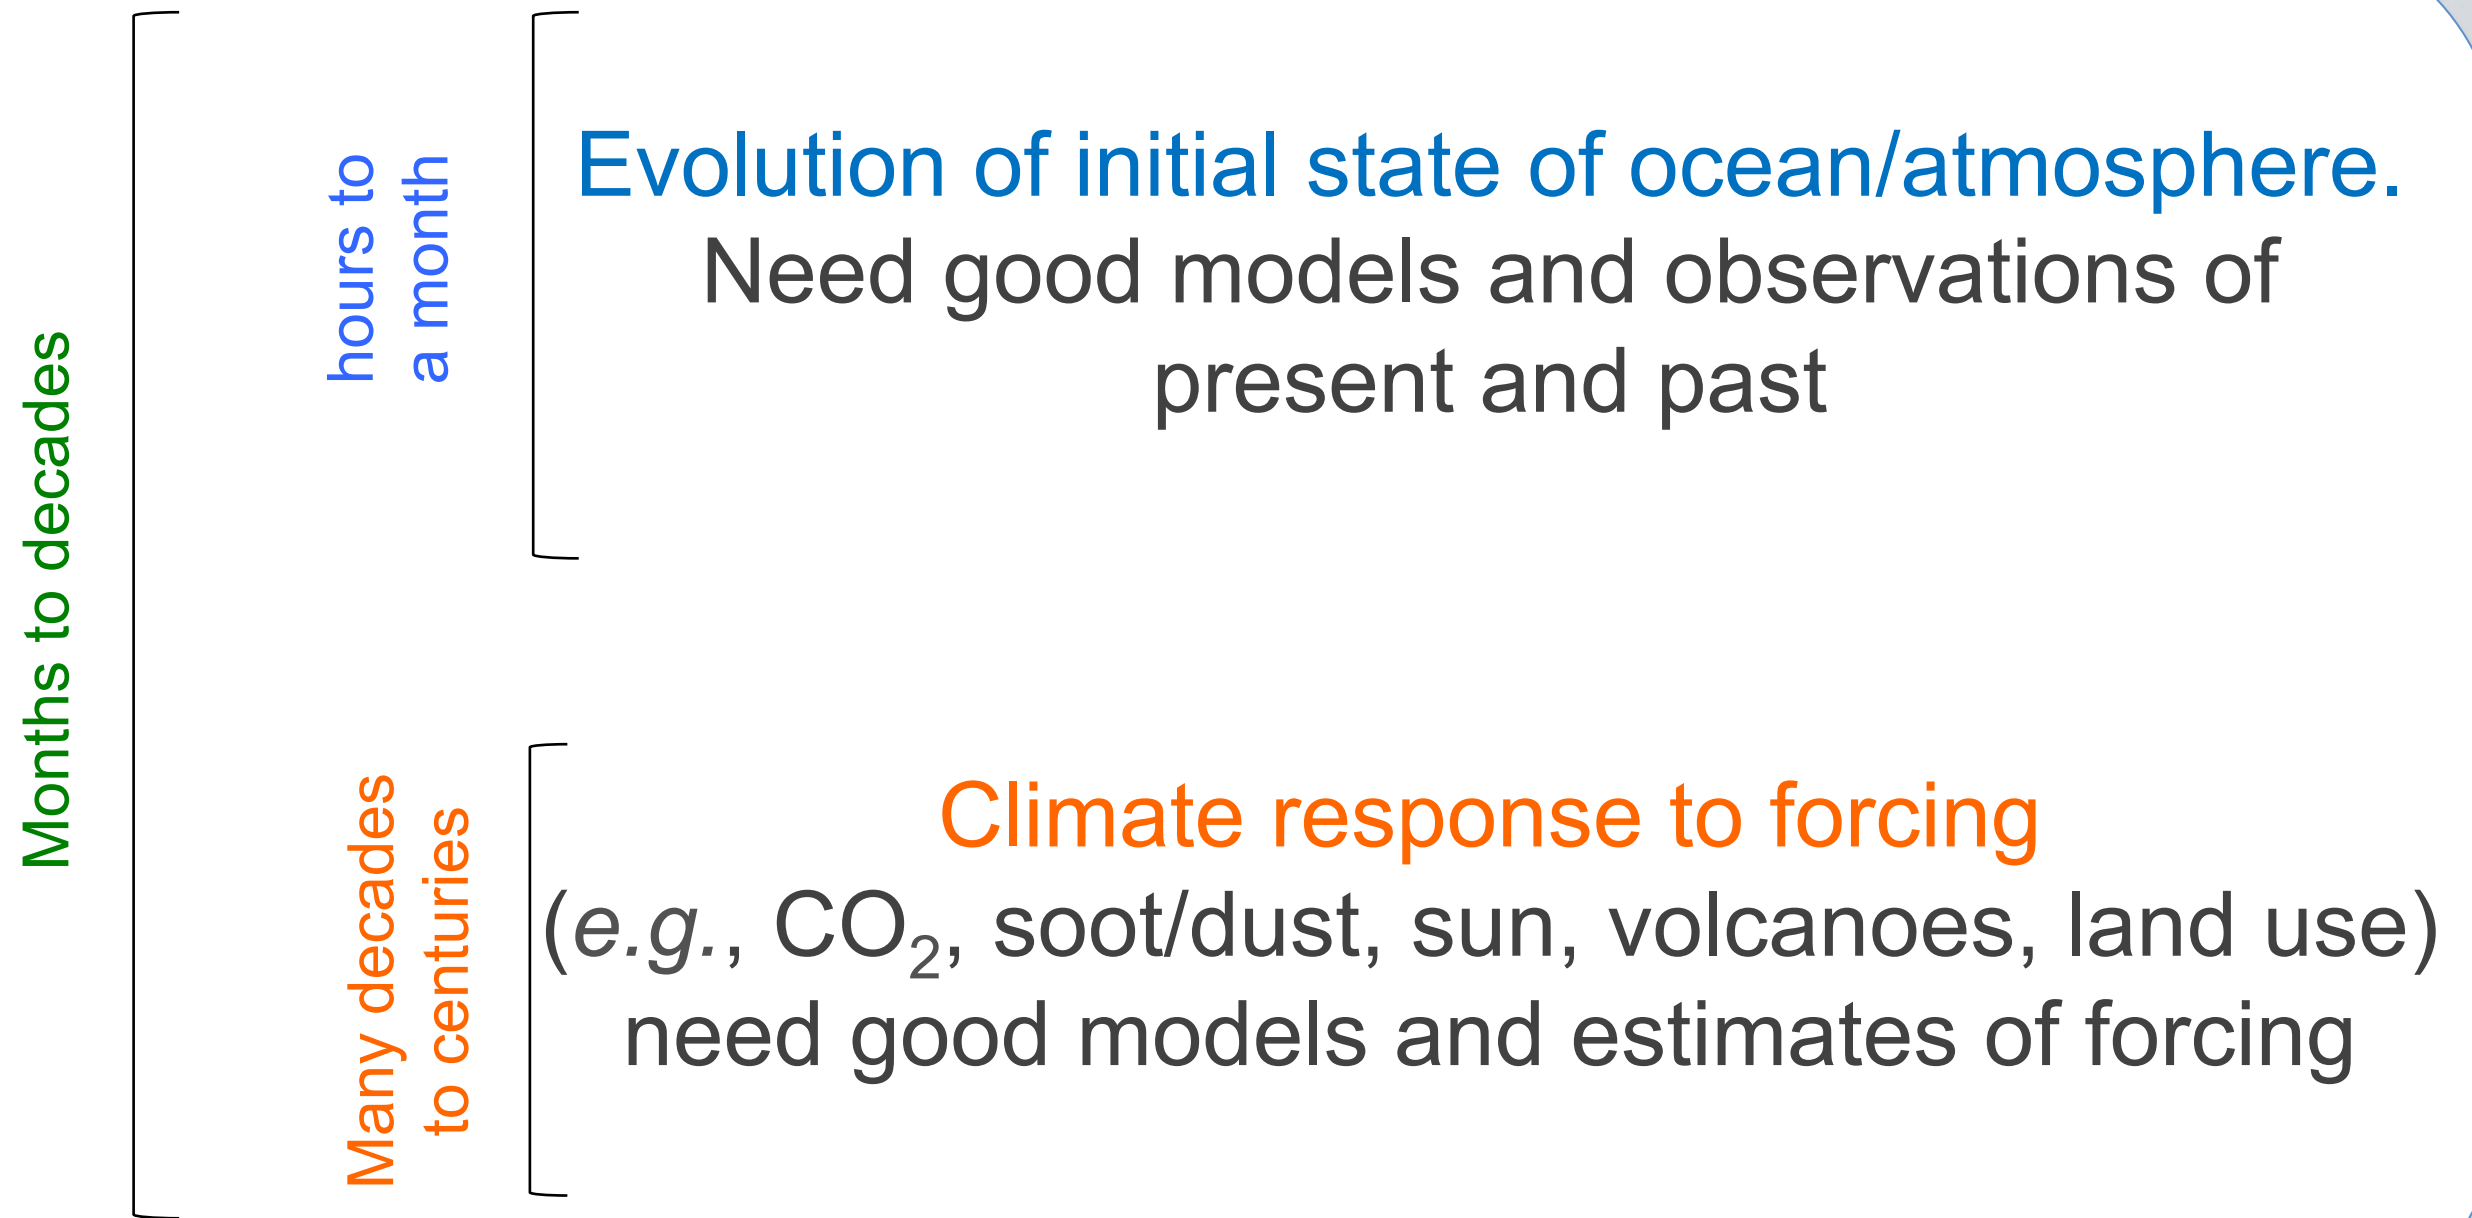

Introduction to basis, tools, limitations and ways of improving predictions

# Why make predictions?

- **Pragmatic reasons:** skillful predictions help support decisions by providing glimpses of the future.
- **Scientific reasons:** prediction is a fundamental element of scientific method, providing tests to hypotheses underlying them.

# Sources of & Limitations on Climate Predictability

Predictability has inherent limits: need to be probabilistic.

# Elements of Climate Prediction System of Systems

Image sources: NOAA/PMEL and  
Argo.ucsd.edu

Global climate observing system:  
Sparse observations of many  
quantities across globe.

Dynamical modeling system:  
Allows forward integration from  
present state, including expected  
changes in radiative forcing.

Data assimilation system:  
Combines sparse observations with  
model, to estimate present state.  
Usually based on dynamical model.

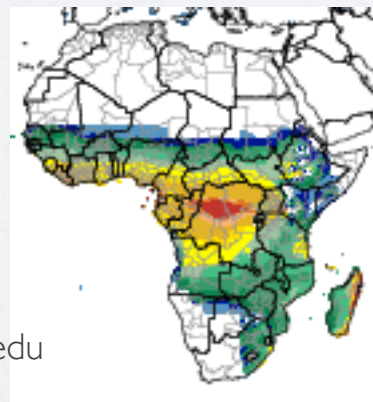

Image source: <http://iridl.ldeo.columbia.edu>

Analysis and dissemination system:  
Take output from predictions and  
produce “useful” information,  
communicate predictions.

# Global dynamical model:

Mathematical representation of processes controlling ocean, atmosphere, land and ice system (and their interactions)

In each grid cell:

Resolved processes:

- conserve momentum ( $F = m \cdot a$ )
- conserve mass & energy (radiation, latent, etc...)
- account for changes in composition

Parameterized processes:

- spatial/temporal resolution or understanding limit explicit solution.
- e.g., clouds, convection, etc.
- key to much of uncertainty

“Initialize” to observationally-constrained estimate of present state.  
“Force” with solar radiation, structure of continents, land use and atmospheric composition ( $\text{CO}_2$ ,  $\text{O}_3$ , aerosols, volcanoes, etc.)

High-resolution GFDL climate model (CM2.5)  
produces one of best global surface climate  
simulations of present model generation

Faster computer (GAEA)  
allows improved  
resolution that translates  
into significantly reduced  
biases in CM2.5 relative  
to CM2.1

CM2.5 described in Delworth et al. (2012) and companion papers

# Sources of Forecast Uncertainty

- **Inherent predictability limits:** (depends on phenomenon and timescale generally leads to random errors; even “best possible” prediction system not perfect, with possibility of large failures at some point.
- **Potentially predictable variations**
- **Observations (& Assimilation System)**
  - sparse data coverage, inhomogeneity
- **Forcings:**
  - future CO<sub>2</sub>, dust, sun, volcanoes unknown to some degree
- **Models:**
  - Systematic errors, inability to represent processes & phenomena
- **Errors in analysis and communication**

# Dealing with Forecast Uncertainty

- Learn to live with irreducible uncertainties.

- “Noise” or natural variations:

Some unpredictable: probe noise via “single-model ensembles”, parallel experiments with slight perturbations to initial state.

Some may be predictable: start model close to present state of world

- Systematic model errors (“biases”):

- Improve model:

- Enhanced comprehensiveness

- Increased resolution

- Better parameterizations (things not explicitly represented)

- Adjust for biases during and/or after forecast

- “Wisdom of crowds” – some errors are different for different models, multi-model ensemble

# Simulated Atlantic Sea Surface Temperature shows impact of climate variability (based on GFDL CM2.1)

Radiative forcing leads to warming, but interspersed by variations in any one of the “equally likely” ensembles.

Can we predict the trajectory of Atlantic temperatures over the next several decades?

How about hurricane activity?

Slide: Tom Delworth (GFDL)

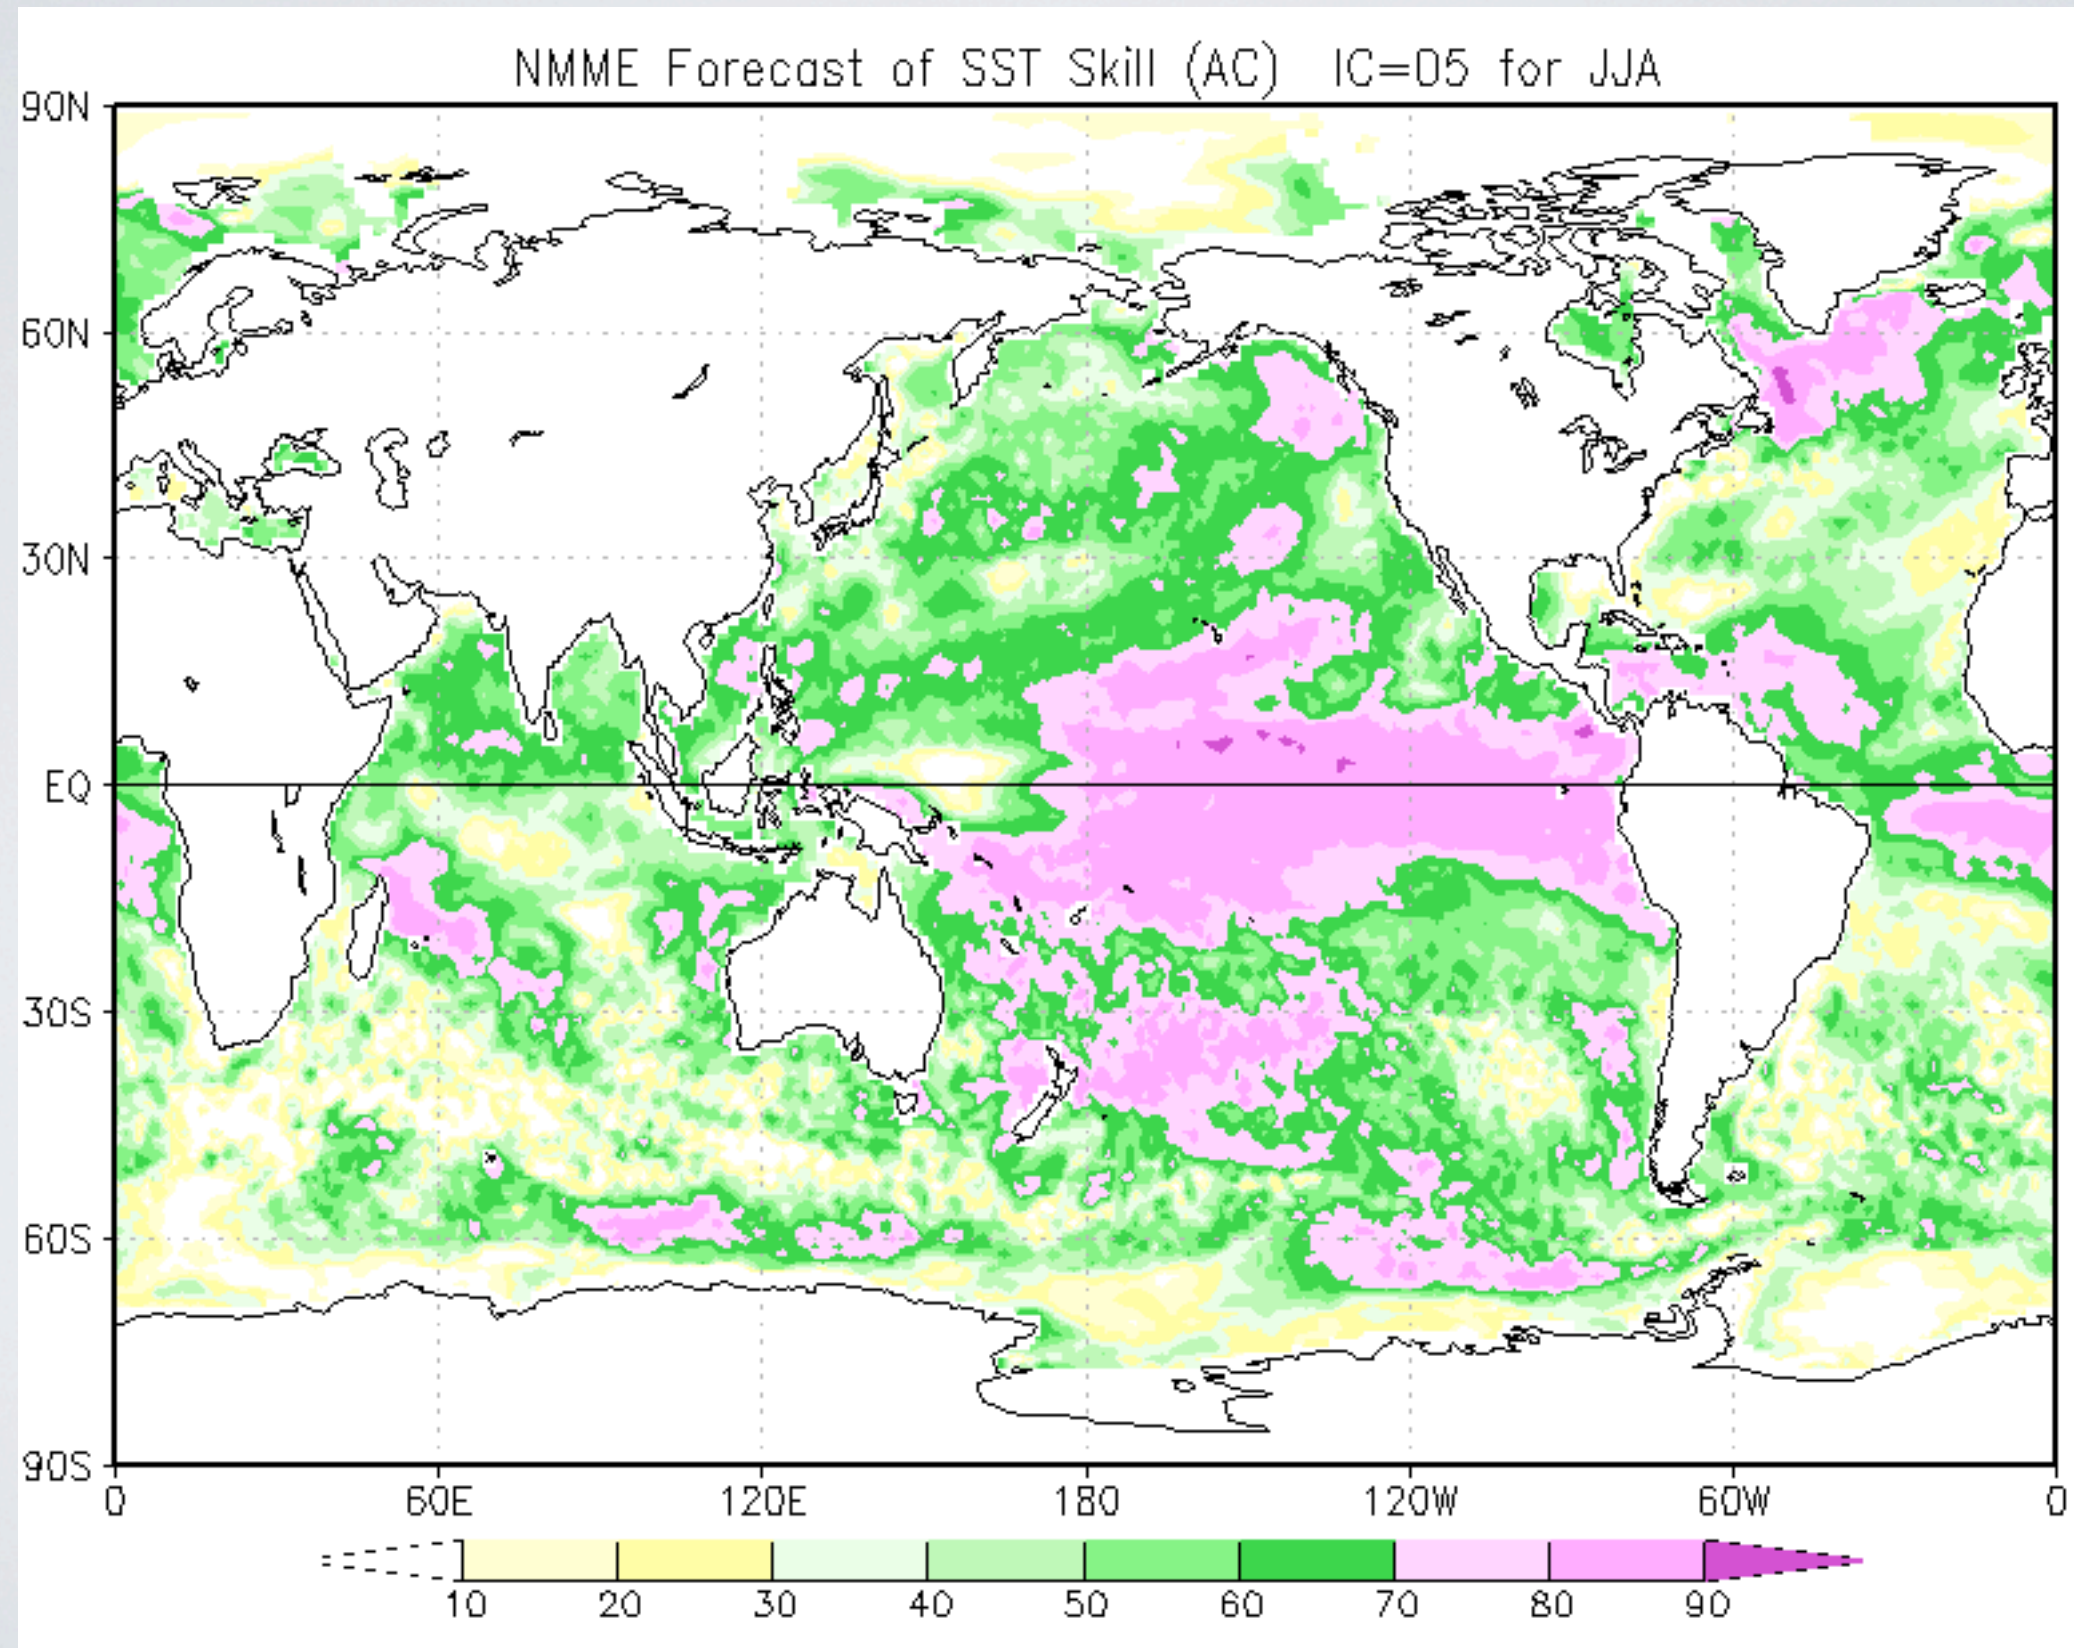

# Predicted NIÑO3.4 SSTA showing inter-model (“epistemic”) and inter-ensemble (“aleatory”)

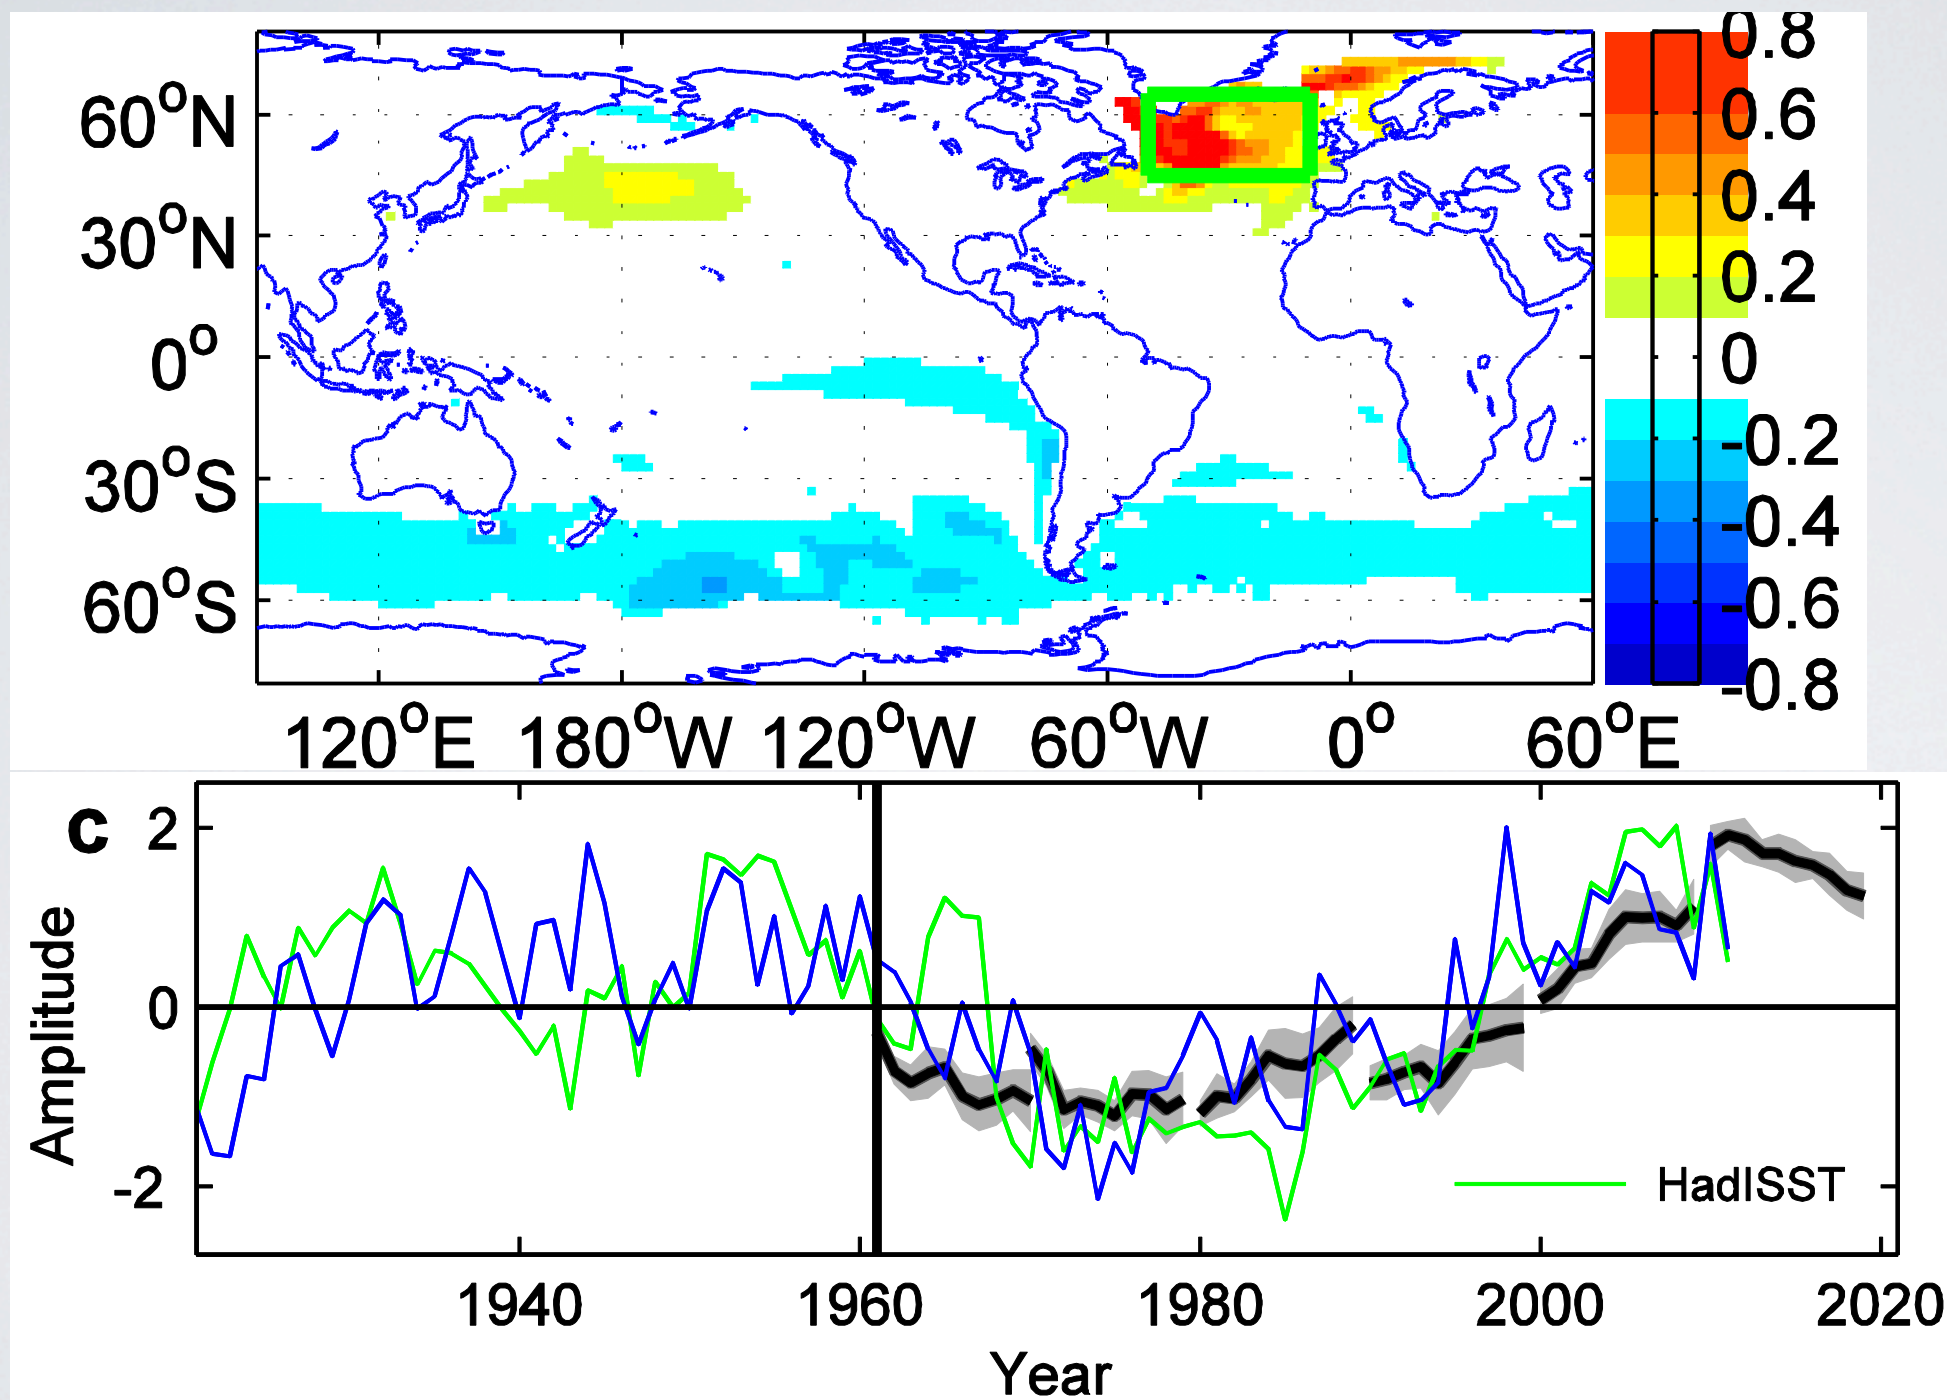

Tropical Pacific and a number of other regions highly predictable (sometimes) on year-to-year timescales

# Aspects of Internal Variability Can be Source of Predictability: Initialization Enables Prediction of 1994-5 Shift in Sub-Polar Gyre

Most Predictable Sea Surface Temperature Pattern 2-9 years in advance

*Yang et al. (2013)*

# “Perfect” ensemble reforecasts indicate inherent multi-year unpredictability

**This is what *perfect* probabilistic forecasts look like!**  
(perfect model, near-perfect initial conditions, 40 members)

(a) Quiet epoch (30yr)

(b) Mega-ENSO epoch (30yr)

# Model resolution

- Increasing model resolution can, in principle, improve predictions by:
  - allowing parameterized some processes become resolved
  - represent features (e.g., topography) better
  - resolve new phenomena (e.g., eddies, storms)
- Increasing model resolution can complicate by:
  - increasing run cost (2x spatial resolution  $\rightarrow$   $\sim 8x$  cost)
  - increasing data volume
  - analysis more difficult
  - initialization not always scale independent
  - “prettier” creates – possibly false – impression of “better”

Increasing model resolution can lead to different answers:  
e.g., Atlantic response to  $2\times\text{CO}_2$  (Saba et al. submitted)

CM2.1

$1^\circ$  ocn.  
200km atm.  
(Delworth et al. 2006)

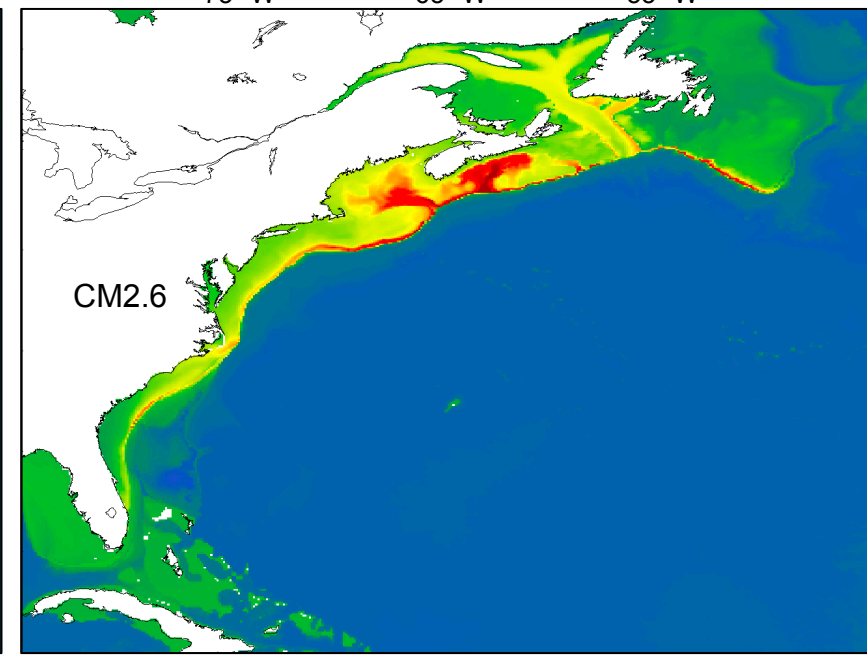

FLOR

$1^\circ$  ocn.  
50km atm.  
(Vecchi et al. 2014)

CM2.5

$0.25^\circ$  ocn.  
50km atm.  
(Delworth et al. 2012)

CM2.6

$0.1^\circ$  ocn.  
50km atm.  
(Delworth et al. 2012)

Bottom ocean temp response to  $2\times\text{CO}_2$  (K)

**GFDL FLOR:** Experimental high-resolution coupled seasonal to decadal prediction system

**Goal:** Build a seasonal to decadal forecasting system to:  
Yield improved forecasts of large-scale climate  
Enable forecasts of regional climate and extremes

Precipitation in Northeast USA

High resolution  
(CM2.5-FLOR)

Medium  
resolution  
(CM2.1)

*Delworth et al. (2012), Vecchi et al. (2014)*

Modified version of CM2.5 (Delworth et al. 2012):

- 50km cubed-sphere atmosphere
  - 1° ocean/sea ice (low res enables prediction work)
- ~15-18 years per day. Multi-century integrations. 4,700+ model-years of experimental seasonal predictions completed and being analyzed.

# FLOR forecast data freely available from GFDL and NMME – model public

4700+ years of forecast data freely available  
(33 years, 12 start months, 12 ensembles)

## GLOBAL CLIMATE MODELS, CM2.5 and FLOR

### CM2.5

The CM2.5 model (Delworth et al., 2012) is a descendant of the GFDL CM2.1 model (Delworth et al., 2006) that incorporates higher spatial resolution and a significantly improved land model (LM3). As a result of these enhancements, the CM2.5 model has a significantly improved simulation of many aspects of climate, particularly hydroclimate over continental regions (Delworth et al., 2012, Figures 5,6,7 and 9) and aspects of ocean circulation. This improvement has allowed GFDL scientists and their collaborators to use this model for innovative studies of regional hydroclimate change (Doi et al, 2012,2013; Kapnick and Delworth, 2013; Delworth and Zeng, 2014; Kapnick et al., 2014) and ocean circulation (Lee et al, 2013). The model has also proven very effective at simulating climate extremes, such as tropical cyclones (Kim et al., 2014) and drought (Delworth et al., 2015). A similar horizontal spatial resolution is being targeted for GFDL's next-generation model, CM4.

Since the high-resolution ocean model is relatively expensive to run, a companion model (see description on this web site for CM2.5\_FLOR) was developed using the same atmospheric component as CM2.5, but with a lower resolution (and therefore much faster) ocean model. This has proven very effective for seasonal to interannual prediction, especially given the need for very large sets of simulations to assess the skill of a prediction system.

#### Model details

The atmospheric component of CM2.5 has similar physics as CM2.1, but uses grid box cells that are 50 Km on a side, versus approximately 200 Km in CM2.1. The atmospheric component also increases the number of vertical levels from 24 to 32. The ocean component has horizontal resolution of

# Multi-model ensembles

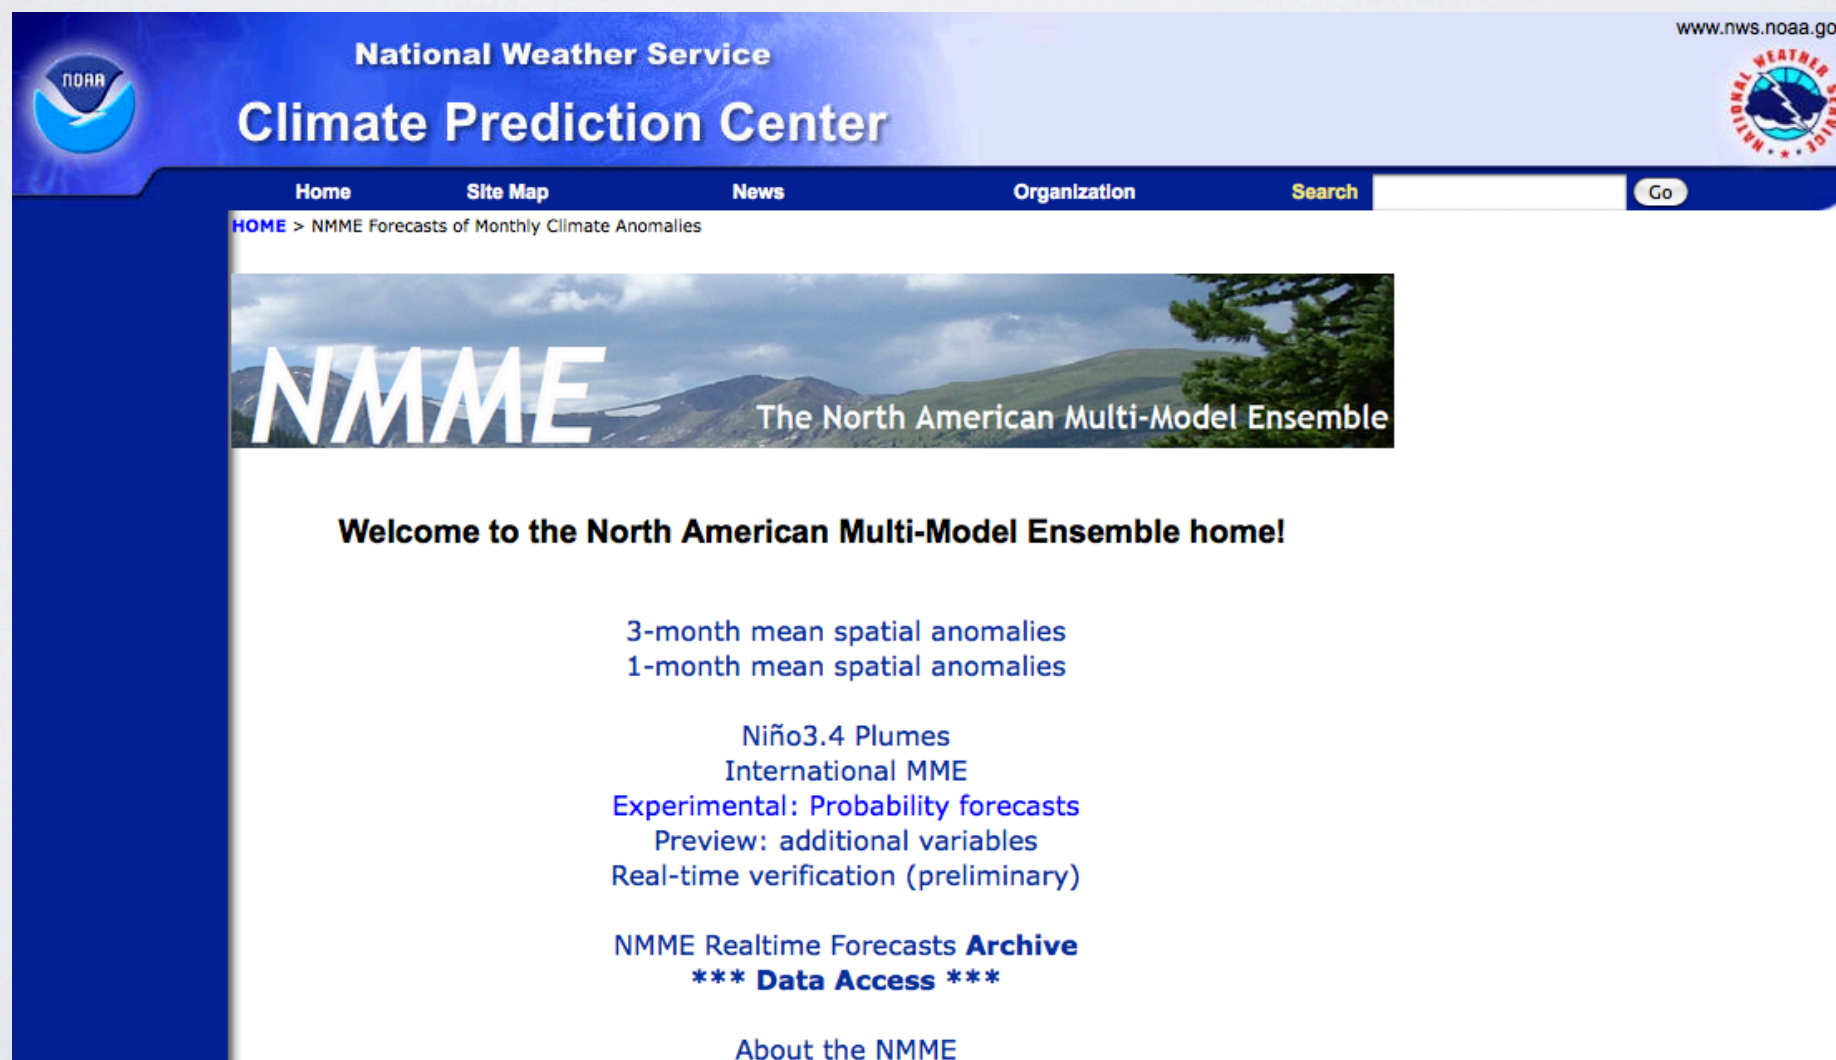

“Wisdom of the crowds”

- Many model errors differ across models
- Hypothesis: Looking across multiple models will:
  1. Yield a more reliable prediction
  2. More accurately represent true prediction uncertainty

# North American Multi-model Ensemble for Seasonal Prediction (NMME)

- NOAA-led, interagency (& international – U.S.A. & Canada) effort
- Every month predictions from multiple models combined.
- Data & analysis publicly available:  
<http://www.cpc.ncep.noaa.gov/products/NMME/>

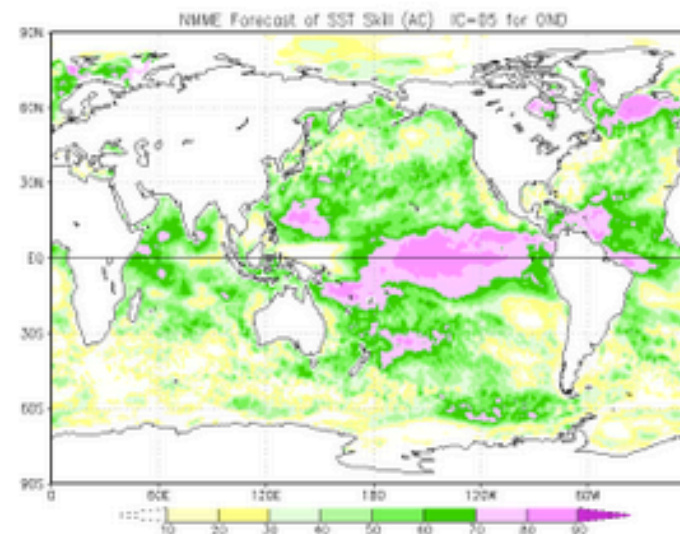

NMME tends to outperform individual models (OND SST forecast from 1-May)

# Summary

- Both changes in external conditions (e.g., CO<sub>2</sub>, dust, volcanoes) and internal variations (e.g., El Niño, Overturning circulation) are basis for prediction.
- There are inherent limits to predictability:  
**need to think probabilistically** in forecast production, use and evaluation depend on scales and phenomena.
- **Enhanced computing** enables the development of high-resolution dynamical models.
- Multi-model techniques tend to yield more reliable predictions
- Errors in large-scale simulation a key source of biases in simulation/prediction of regional climate and extremes
- **Partnerships and co-development** can facilitate development of new prediction applications – and reduce risk of misuse of predictions
